CALNIVO — COMBINED AUDIT & REQUIRED CHANGES

Implementation plan based on the Full Website Audit and SEO Master Checklist

Prepared: 16 October 2026

PRIMARY GOAL: Fix accuracy and trust first, then technical SEO, page quality, and authority. Keep Calnivo's existing 40 calculators and current design; do not expand scope unnecessarily.

Purpose and scope

• Combine the findings from (1) the Calnivo Pre-AdSense Full Website Audit and (2) the uploaded SEO Master Checklist. This document lists the changes that are justified by those audits and provides a concise implementation prompt.

• Project constraints: preserve the existing Next.js architecture, design/UI, routes, and working functionality; keep the existing 40 calculators; do not add hundreds of calculators; do not add spreadsheet/Excel functionality; do not claim fixes, indexing, rankings, or AdSense approval without verification.

• Important: these are audit findings and required actions—not a statement that the fixes have already been implemented. Re-check each issue in the current repository before changing code.

Priority 0 — Fix correctness and trust risks first

• 1. Tax calculator: the current implementation uses IRS 2024 federal brackets. Explicitly state the supported tax year and jurisdiction, verify all figures against authoritative IRS material, and either update to the intended supported year or clearly label the calculator as historical. Ensure deductions, filing statuses, and limitations match what the tool actually calculates.

• 2. Privacy policy and footer claims: reconcile statements such as “no data collected,” “100% client-side,” and no analytics/advertising with actual code, hosting logs, third-party scripts, cookies, and any services used. Explain that local calculation inputs can remain in the browser while hosting providers may process request metadata. Update the policy before adding ads or analytics.

• 3. Formula correctness across all 40 calculators: independently verify formulas, units, rounding, assumptions, invalid inputs, zero/negative values, decimals, extreme values, and edge cases. Keep internal precision and round only for display where appropriate. Add regression tests with known expected answers.

• 4. Health and finance claims: ensure calculators describe estimates and limitations honestly. Do not imply diagnosis, guaranteed investment outcomes, or medical certainty. Use suitable disclaimers and authoritative sources where the method or data requires them.

Priority 1 — Repair known implementation/content mismatches

• 5. Inflation calculator: remove the unfinished “Scenario comparison will appear here” message; verify deflation and boundary cases so they do not produce misleading results; audit the real-return/purchasing-power logic and display only values that are meaningful for the selected inputs.

• 6. BMI calculator: make the page's claims match its implementation. The standard BMI formula does not use the entered age/gender; do not imply pediatric BMI-percentile calculations unless those are actually implemented and verified. Clarify intended scope and limitations.

• 7. Age calculator: replace the hardcoded 2024-01-01 reference date with a sensible current-date default or another clearly intentional default. Verify leap years, date ordering, and boundary cases.

• 8. Salary calculator: correct the mismatch between the vacation/holiday explanation and the weeks-per-year arithmetic. Make the chosen assumption explicit and test all wage conversions.

• 9. Pregnancy / due-date calculators: validate the cycle-length range consistently with the UI; validate dates; explain that due dates and conception dates are estimates and that conception cannot be established precisely by a simple date calculation.

• 10. Other calculator-specific checks: verify Body Fat method and measurement constraints; Retirement contribution timing and return assumptions; Amortization schedule totals and caps; Loan edge cases; Grade weighting and grade-scale limitations; Password Generator duplicate exclusion options and entropy/strength estimate. Correct only issues confirmed by testing.

• 11. Remove or complete all scenario-comparison placeholders. If a scenario feature is not implemented, remove the promise/empty placeholder rather than implying functionality exists.

Priority 1 — Technical SEO and indexing

• 12. Sitemap: stop assigning the same build-time timestamp to every URL. Omit lastModified when a reliable page-specific update date is unavailable; otherwise use truthful, page-specific significant-update dates.

• 13. Canonical/indexability: verify all intended public pages return correct status codes, have one correct canonical, are not accidentally noindex, and are consistent between www and non-www/HTTPS variants. Review redirects, 404s, server errors, duplicate URLs, and redirect chains.

• 14. Sitemap and robots: ensure sitemap.xml is valid, contains only intended canonical/indexable URLs, and robots.txt points to it without blocking important pages or resources. Confirm sitemap submission in Search Console; submission is not a guarantee of indexing.

• 15. Structured data: validate Organization, WebSite/WebApplication where accurate, and BreadcrumbList against visible page content. Review/remove FAQPage markup if inappropriate; keep useful visible FAQs. Do not add Article, Product, LocalBusiness, or Event schema unless the page genuinely represents that entity/type.

• 16. CSP/security: review Content Security Policy before adding advertising or analytics, but do not remove security protections wholesale. Test all scripts, styles, images, fonts, and connections needed by the current site and any explicitly approved future services.

• 17. Performance/accessibility: measure mobile and desktop performance, Core Web Vitals (LCP, INP, CLS), JavaScript/CSS overhead, fonts/images, layout shifts, keyboard access, contrast, form labels, and tap targets. Fix evidence-backed issues without redesigning the site.

Priority 1 — Page quality, SEO, and trust

• 18. Review all 40 calculator pages for unique, accurate titles/meta descriptions, one clear H1, logical headings, readable content, relevant internal links, and alignment between visible claims and actual calculator behavior.

• 19. Improve page-specific value: formula/method, definitions and units, verified worked example, input assumptions, result interpretation, limitations, and genuinely useful FAQs. Avoid generic repeated blocks, keyword stuffing, or word-count padding.

• 20. Use meaningful related-calculator links and descriptive anchor text. Keep navigation and the calculator directory crawlable. Do not create a giant footer or unnecessary URLs merely to influence crawling.

• 21. Trust pages: make About, Contact, Privacy, and Terms easy to find and accurate. Explain formula methodology/testing where supportable. Do not invent qualifications, expert reviewers, testimonials, statistics, or editorial credentials.

• 22. Source changing facts: identify relevant authoritative sources and supported tax year/jurisdiction for tax-related calculations; document sources and dates for other changing datasets where used. Distinguish sourced facts from estimates and assumptions.

• 23. AEO/AI-search readiness: answer the main question directly, define key terms, explain formulas in plain language, show accurate examples, cite authoritative sources where useful, and ensure important explanations are crawlable and not hidden behind inaccessible interactions. Do not promise AI citations or rankings.

Priority 2 — Off-page SEO and monitoring

• 24. Review the actual backlink profile and competitor link gaps before proposing outreach. Pursue relevant, legitimate mentions and useful original resources; avoid paid/spammy link schemes, mass-produced guest posts, and artificial reviews.

• 25. Keep Calnivo's organization name and description consistent across legitimate profiles and publications. Use local SEO/Google Business Profile only if the business genuinely qualifies.

• 26. Use Search Console URL-level exports to classify pages as indexed, crawled-not-indexed, discovered-not-indexed, duplicate/canonical, redirected, not found, server error, or blocked. Do not assume sitemap inclusion or HTTP 200 means a page is indexed.

• 27. Establish a practical review cadence: daily critical errors/security/uptime; weekly indexing, 404s, and page changes; monthly content, performance, and crawl review; quarterly full content, technical, and backlink audit.

Implementation order and acceptance criteria

• Stage A — Baseline: audit all checklist items and all 40 calculators. Record PASS / FAIL / PARTIAL / NOT TESTED with evidence and file/URL references. Do not mark untested items as passed.

• Stage B — Correctness and trust: fix verified calculation defects, stale tax data/labels, privacy contradictions, and misleading or unfinished features.

• Stage C — Technical SEO: fix sitemap dates, canonicals, indexability, redirects, structured data, security configuration, and verified performance/accessibility issues.

• Stage D — Page quality and AEO: improve only pages that need improvement, using specific methodology, examples, assumptions, limitations, sources, and relevant links.

• Stage E — Regression: run lint, production build, route tests, all-calculator expected-answer tests, responsive tests, sitemap/metadata/schema checks, and privacy/security checks.

• Definition of done: every change has evidence; all 40 calculators pass defined expected-answer tests or have clearly documented unresolved issues; existing routes/UI/functionality remain intact; the final report lists changed files, tests, PASS/FAIL/PARTIAL/NOT TESTED items, and remaining blockers. Do not claim Google indexing or ranking gains without Search Console evidence.

SHORT IMPLEMENTATION PROMPT

CALNIVO — COMBINED AUDIT FIX

```
Use the attached Calnivo Full Website Audit and SEO Master Checklist as the source of truth. Audit the current repository first, then implement only verified, necessary fixes across all 40 existing calculators, formula accuracy, tax-year/data labels, privacy/trust claims, unfinished placeholders, calculator-specific content, on-page SEO, sitemap/canonicals/robots, structured data, security/CSP, performance/accessibility, and AEO readiness. Preserve the existing Next.js architecture, UI/UX, routes, formulas unless a defect is verified, and all working functionality. Do not add calculators, spreadsheet/Excel features, keyword stuffing, invented credentials, or unrelated redesigns. Test every calculator against known expected outputs and edge cases; run lint, production build, route/SEO/schema checks, and mobile/desktop regression tests. Return a checklist with PASS/FAIL/PARTIAL/NOT TESTED, evidence, changed files, tests, and unresolved issues. Do not claim completion, indexing, rankings, or AdSense approval without proof.
```
